REQUIREMENT ANALYSIS

Technology Stack & Technical Architecture

Automated Network Request & Fulfillment Management System

Date	5 September 2026
Student Name	Bantupalli Niharika
Project Name	Automated Network Request & Fulfillment Management System
Platform	ServiceNow

1. Technical Architecture

The solution is designed on the ServiceNow platform. Employees submit network-related requests through a service portal or catalog experience. The platform validates the submitted information, routes the request for approval where required, and creates or assigns fulfillment tasks to the responsible support group.

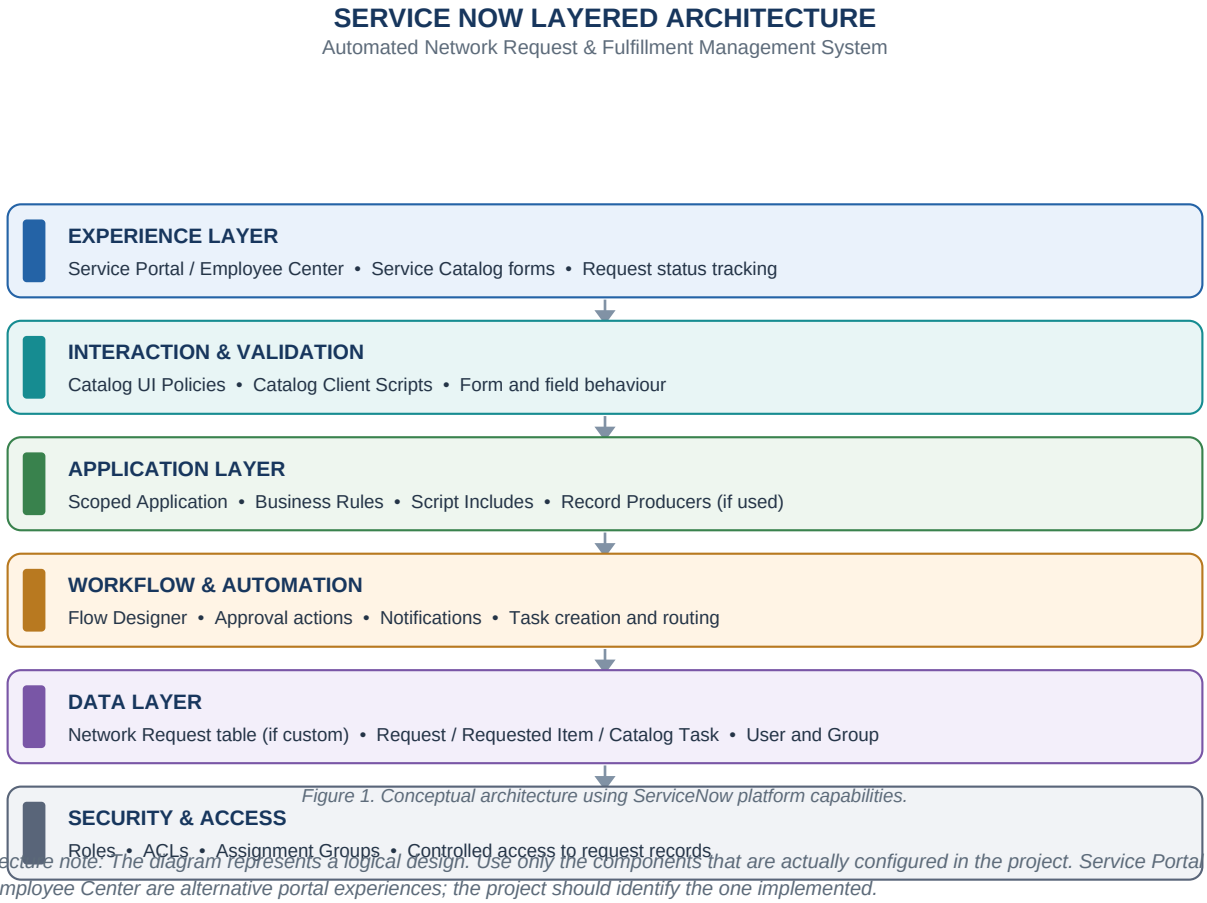

Figure 1. Conceptual architecture using ServiceNow platform capabilities.

Architecture note: The diagram represents a logical design. Use only the components that are actually configured in the project. Service Portal and Employee Center are alternative portal experiences; the project should identify the one implemented.

2. Technology Stack Summary

1	**User Interface**	Provides an employee-facing interface to submit network requests, enter required details and track request progress.	Service Portal or Employee Center; Service Catalog item and catalog form
2	**Application Logic**	Processes request information and applies project-specific business logic.	Scoped Application; Business Rules; Script Includes; Record Producers (if used)
3	**Form Validation**	Makes fields mandatory or visible as needed and validates user input before submission.	Catalog UI Policies; Catalog Client Scripts

4	**Data Management**	Stores request details and connects them with request, task, user and group records.	Custom Network Request table (if configured); Request [sc_request]; Requested Item [sc_req_item]; Catalog Task [sc_task]; User [sys_user]; Group [sys_user_group]
5	**Workflow Automation**	Coordinates approvals, notifications, task creation and request progression.	Flow Designer; Approval actions; Notifications
6	**Fulfillment**	Routes approved work to the appropriate team and supports assignment and completion of network tasks.	Catalog Tasks; Assignment Groups; task assignment rules or flow logic
7	**Security & Access**	Controls who can view, submit, update or approve requests and related records.	User Roles; Access Control Lists (ACLs); group-based access

3. Component Responsibilities

The following points describe how the main platform components work together in the request lifecycle.

Activity	Responsibility
Request submission	An employee opens the service catalog item, enters network request details and submits the form. The platform creates the corresponding request records.
Input validation	Catalog UI Policies and Catalog Client Scripts control field visibility, mandatory status and client-side validation. Server-side checks should be used where data integrity must be enforced.
Business processing	The scoped application contains project-specific logic. Business Rules and Script Includes can support reusable processing where required.
Approval and routing	Flow Designer can evaluate request conditions, initiate approval steps, send notifications and route work to the relevant assignment group.
Fulfillment and closure	Catalog Tasks are assigned to support teams. The team updates task status and completes the assigned work; the request is progressed according to the configured workflow.
Access control	Roles and ACLs restrict access to records and actions based on the responsibilities of employees, approvers and fulfillment teams.

4. Important Technical Clarifications

• **Standard tables vs. custom table:** REQ, RITM and Catalog Task records are standard ServiceNow request-management records. A custom Network Request table should be listed only if the project actually creates and uses one. Avoid presenting the same request data as being stored in multiple places without explaining the relationship.

• **Portal choice:** Service Portal and Employee Center are not two names for the same interface. Mention the portal experience that is implemented in the instance; retain the other only as an alternative if relevant.

• **Client-side vs. server-side logic:** Catalog Client Scripts and Catalog UI Policies support form behaviour. Business Rules and Script Includes are used for server-side processing and reusable application logic.

• **Technology scope:** AngularJS and generic UI/API references have not been retained as core stack items because the source document does not establish that custom AngularJS development or a separate API integration is part of this implementation.

5. End-to-End Request Flow

1. Submit Request	2. Validate Details	3. Approval (if needed)	4. Create / Assign Task	5. Fulfill & Close
Employee submits the catalog form.	Policies and scripts validate the form.	Flow Designer manages approval routing.	Task is routed to the responsible group.	Support team completes work and updates status.

Implementation reminder: *Before final submission, confirm the actual portal used, whether a custom Network Request table exists, and which approval and task-routing steps are configured. This document describes the recommended logical stack and should match the implemented application.*
